Subject: Contract No. DAAE07-85-C-R094  
Final Technical Report

Gentlemen:

In accordance with the reporting requirements set forth in Contract Data Requirements List Exhibit "A" (DD Form 1423) under the subject contract, enclosed please find a reproducible original and four (4) copies of the Final Technical Report (Sequence No. A003). This report incorporates those corrections enclosed with your letter dated February 12, 1987.

The remaining copies of the Final Report have been sent in accordance with the distribution list. Also enclosed are four (4) copies of DD Form 250 for your execution. This completes our reporting requirements under the subject contract.

We are pleased to have had this opportunity to be of service to the U.S. Army Tank Automotive Command.

Very truly yours,

S. J. Chrapkowski  
Contracts Manager

SJC/dd

19. ABSTRACT (Continue on reverse if necessary and identify by block number) A microcomputer-controlled ultrasonic Automated Depot Roadwheel Inspection System was reprogrammed to incorporate a mathematical model for estimation of the adhesion strength of the rubber-to-metal bonding based on selected ultrasonic parameters. Additionally, accept/reject criteria for weak bonding and undercure were modified along with certain characteristics of the microcomputer control of the hardware of the system. A 6-month field test was run with this modified configuration to assess the correlation of the ultrasonic inspection system predictions of roadwheel quality with the quality determined by in-production destructive testing. The success of adhesion failure prediction in this test is discussed, along with the need for further data analysis for enhanced strength prediction and hardware/software modifications to allow reliable separation detection.

## PREFACE

The work described in this report was performed by Chamberlain Manufacturing Corporation, GARD Division, 7449 North Natchez Avenue, Niles, Illinois 60648, for the U. S. Army Tank-Automotive Command (TACOM) under Contract No. DAAE07-85-R-R100. The work was administered under the direction of Army Project Engineer Larry McNamara of TACOM, Warren, Michigan.

The work was performed by the Electronic Systems Group, of the GARD Division, W. Lichodziejewski, Manager, by I. R. Kraska, Project Engineer with the assistance of B. H. Hill and T. A. Mathieson.

The authors gratefully acknowledge the assistance provided by the Army Project Engineer, by the Red River Army Depot Material Quality Control Department personnel supervised by R. M. Rumbo, and by William Bono at Red River Army Depot.

This report covers work conducted during the period of September 1985 to August 1986.

## 1.0 INTRODUCTION

This report presents the results of an effort to upgrade the GARD-developed Automated Depot Roadwheel Inspection System (ADRIS) and test the feasibility of it replacing the destructive peel-strength test presently in use at Army depots. The ADRIS was the result of these original goals, combining an automated ultrasonic scanning configuration adjustable for different roadwheel sizes with microcomputer communication and control for simplicity of operator interaction and interpretation. This is the latest phase of a project originated to ultrasonically inspect roadwheel production and provide depot-level personnel with simple accept/reject criteria for roadwheel quality control.

Herein, the firmware of the ADRIS was extensively modified, its hardware was augmented, and a 6 month field test at Red River Army Depot was supported.

This report will present a summary of the modifications made to the ADRIS hardware and firmware along with a discussion of their implications. Then a detailed examination of the field test results will be presented.

## 2.0 OBJECTIVES

The aim of the present phase of the project was to modify the ADRIS firmware to include adhesion estimation equations developed by United Technologies Research Center under Contract Number DAAE07-84-M-R024 and to assess the validity of these equations for predicting adhesion strength of roadwheel rubber-to-metal bonding under production quality control conditions.

## 3.0 CONCLUSIONS

During the field test, 367 roadwheels were inspected using the ADRIS; 166 of these were subjected to destructive peel-strength testing to corroborate ADRIS indications. From these destroyed roadwheels, over 3,700 data pairs for each of 5 ADRIS outputs were used in 3 types of correlation of ADRIS adhesion estimation with destructively measured adhesion strength. Although the data showed monotonically varying trends of estimated adhesion with measured adhesion, estimation of peel-strength by the ADRIS yielded no correlation coefficient greater than 0.80. This low value is likely due to corrupting factors in the destructive peel test which could not be compensated for in the data selection and analysis.

However, ADRIS prediction of adhesion failure was more successful. Three roadwheels failed the peel test because of poor adhesion, and the ADRIS was able to reliably predict these failures with no overcall or undecall. However, peel testing allows acceptance/rejection of roadwheel lots on criteria other than adhesion failure alone. Presence of separations, contamination, and "poor workmanship" are visually assessed during peel testing. Evidence of separation presence was the principal mode of roadwheel rejection found during this field test, occurring in 20 percent of

the roadwheels tested. Because of current hardware and firmware configuration, the ADRIS performed poorly in predicting this cause of failure, yielding an average detection rate of 42 percent and an average overall rate of 61 percent. Further, the ADRIS is not currently capable of detecting the presence of contamination or rejectable cosmetic faults.

Roadwheel adhesion failure prediction by the ADRIS was demonstrated in three cases with a reliability of 100 percent. If this was the only measurement required for acceptance/rejection, the ADRIS could be adequately configured for production use. Further observation of roadwheel adhesion failures while monitoring with the ADRIS is required to increase the statistical significance of this conclusion.

Estimation of adhesion strength could not be established to a correlation better than 0.80. The volume of data acquired during the field test is more than that which could be completely examined within the limits of this effort. From preliminary inspection, there appear to be categories into which the data could be sorted which may improve the adhesion estimation performance or may suggest what steps are necessary to improve estimation performance. It is recommended that a follow-on effort examine our current database in greater depth, attempting to provide a better strength measurement correlation.

Separation detection by the ADRIS was found to be no better than an average of 42 percent indications with an unacceptable 62 percent rate of false detections.

#### 4.0 RECOMMENDATIONS

Our recommendation is that separation detection be improved by software/hardware modifications of the ADRIS. These include complete scan across the width of the roadwheel, finer beam resolution through use of smaller diameter transducers or focused transducers, increased processing speed and memory capacity in the controlling microcomputer, and more microcomputer control of front-end signal conditioning.

Incorporation of such modifications may also improve ADRIS detection of contamination and rejectable cosmetic faults.

#### 5.0 DISCUSSION

##### 5.1 ADRIS Modifications

5.1.1 Firmware Modifications. The ADRIS was originally programmed to function primarily as a data-logging device in support of discovering those patterns of ultrasonic reflection data which most reliably indicated presence of debonding, inclusions, and weak bonding in roadwheels. Once such patterns were identified, it was then intended that the ADRIS be reprogrammed to function as a logic-filtering device in support of yielding simple accept/reject decisions on roadwheel quality.

The present phase of the project required that the ADRIS be reprogrammed principally to support the implementation of three specific pattern filters and a computation of estimated adhesion strength. To satisfy the requirements of this reprogramming, the original integer arithmetic algorithms of the ADRIS had to be converted to floating-point form and the computation of three new derived parameters had to be implemented. The new derived parameters are:

$$D_2 = A_2 / A_{BB}$$

$$D_3 = A_3 / A_{BB}$$

$$D_5 = A_5 / A_{BB}$$

where  $A_2$  is the acquired 270 kilohertz (kHz) amplitude

$A_3$  is the acquired 370 KHz amplitude

$A_5$  is the acquired 500 KHz amplitude

$A_{BB}$  is the acquired unfiltered (broadband) amplitude

The specific pattern filters are:

- Weak Bond Test A:

$D_2 \leq 0.40$  for accumulated circumference  $\geq 25\%$

- Weak Bond Test B:

$A_2 \leq 12$  for accumulated circumference  $\geq 40\%$

- Undercure Test B:

$A_2 \geq 22$  for accumulated circumference  $\geq 40\%$

The estimated adhesion equations are:

$$PEEL(i) = C_{31} + C_{32} * X_1(i) + C_{33} * X_2(i)$$

where:

$$X_1(i) = C_{11} + C_{12} * A_3(i) + C_{13} * A_5(i) + C_{14} * A_3^2(i) + C_{15} * A_5^2(i) + C_{16} * A_3(i) * A_5(i)$$

$$X_2(i) = C_{21} + C_{22} * A_5(i) + C_{23} * D_5(i) + C_{24} * A_5^2(i) + C_{25} * D_5^2(i) + C_{26} * A_5(i) * D_5(i)$$

expressed for each sampled circumferential interval  $i$  and the  $C_{jk}$  are adjustable coefficients.

With the introduction of these parameters, tests, and computations, the operational philosophy has distinctly shifted away from that of data logging to that of task specificity. The specific tasks are now to be acceptance and rejection upon detection of the original conditions of phase-inversion debonding and tread rubber inclusions and upon measurement of the new conditions of weak bonding, undercure, and adhesion estimation. The absence of a printed data summary reflects this shift. Additionally, the finding that processing of two channels of data does not materially contribute to corroboration with destructive test data in the case of roadwheels with wider tread has led to the processing and presentation of data averaged across the active channels. This, and the presence of new parameters, are reflected in a modified printout format.

Acquisition of the 110 KHz filtered amplitude has been discontinued with the finding that it does not materially contribute to measurement of road-wheel quality. Finally, the ADRIS firmware has been modified to enable continuous pulsing of the ultrasonic transducers during periods of non-inspection for the purpose of maintaining the stability of the electronics.

**5.1.2 Hardware Modifications.** The implementation of the additional parameters and computations discussed in par. 5.1.1 required such a modification of the ADRIS operation that a larger capacity random access memory (RAM) was needed. This was supplied by the replacement of the original 16 thousand bytes (K) RAM card with a 32K RAM card. Because of the net reduction in number of parameters the ADRIS maintained in its data logging configuration, no enlargement of the battery-backed RAM was necessary.

To support temperature compensation during the field test, an external thermocouple probe and readout were procured.

## **5.2 Field Test**

The ultimate purpose of modifying the ADRIS and testing its predictive accuracy on the production line is to use it to replace the destructive peel-strength test currently employed. The principal benefits to be realized from this are that because the ultrasonic test is nondestructive in nature, product no longer will be sacrificed to quality control and every roadwheel produced can be inspected, thus eliminating statistical sampling and inferential assessment of lot quality.

This section describes the 6 month field test of the ADRIS conducted at Red River Army Depot (RRAD) during the first half of 1986 in support of these goals. A total of 367 roadwheels was inspected using the ADRIS. Of these, 143 were intercepted from production lot samples, dynamometer test samples, or other quality test samples scheduled for routine peel-strength testing. An additional 224 roadwheels were directly sampled from production inventory by GARD personnel in order to discover unusual or anomalous ultrasonic output and to destructively determine the cause by unscheduled peel-strength testing. Of these latter, a total of 23 wheels were purchased from RRAD production for destructive evaluation and correlation with ADRIS output. The roadwheel size groups investigated were:

24 in. by 2.12 in.  
24 in. by 2-1/8 in.  
24 in. by 3-3/4 in.  
26 in. by 5-3/4 in.  
26 in. by 6 in.

Roadwheels of size 32-1/4 in. by 3-1/2 in. were not being produced in sufficient quantity during this period to be subject to normal RRAD quality control and roadwheels of size 28 in. by 2-1/2 in. had to be passed uninspected because the ADRIS has no fixturing to hold this size. Table 5-1 summarizes the population characteristics of the roadwheels examined during this field test.

The peel-strength test procedures presently in force at RRAD address not only adhesive strength of the rubber-to-metal bonding, but also presence of separations, contamination, cosmetic appearance, and other visual quality assessment. The ability of the ADRIS to emulate these aspects of the peel-strength test is discussed in the following sections.

**5.2.1 Adhesive Strength Estimation.** If the ADRIS is to effectively replace the present peel-strength test, it must obviously be able to predict the adhesive strength of the roadwheel rubber-to-metal bond at least as well as the peel test does. Therefore, the principal task of the field test was to measure the correlation of the peel test strength measurements with one or more of the ADRIS outputs to find which output yielded the best prediction and to assess the reliability and accuracy of the prediction.

As performed at the RRAD roadwheel facility, the peel-strength test comprised a preparation phase, a pull phase, and an assessment phase. During the preparation phase, approximately 8 inches in length of rubber tread is cut away from the metal hub to serve as a leader for the adhesion test machine to grip. Guide slits are also cut at this time along the rubber-to-metal interface around the entire circumference on both sides of the wheel. The pull phase is the actual tearing of the rubber-to-metal bond while the load on the tearing mechanism is recorded. During this phase, quality assurance personnel monitor the path of the tear interface and keep it close to the rubber-to-metal interface by judicious cutting and trimming of the rubber. During the assessment phase, personnel inspect the exposed interface for visual defects, record the maximum and minimum peel strengths obtained, and decide the quality of the wheel( and by inference, its source lot).

Attempts to directly correlate ADRIS output with peel-strength as measured in production at RRAD can be misleading because the peel-strength record includes those times when the tear was advancing away from the rubber-to-metal interface into the rubber tread. During such times, quality

Table 5-1. Roadwheel Population Summary

	INTERCEPTED	PURCHASED	NONINTERCEPTED
24 in. by 2.12 in.	21	2	--
24 in. by 2-1/8 in.	46	1	65
24 in. by 3-3/4 in.	3	2	15
26 in. by 5-3/4 in.	32	7	68
26 in. by 6 in.	41	11	53
	—	—	—
Total	143	23	201

assurance personnel are attempting to guide the tear back to the rubber-to-metal interface by heavy cutting and recorded peel-strength typically increases. As a consequence, the self-adhesion of the tread rubber is being measured, not the rubber-to-metal bond strength, which is what we are attempting to correlate with ADRIS output. Figure 5-1 demonstrates the effect of this situation on a typical peel test record. The jagged profile of those areas marked as "cutting" is caused by the slow increases and sudden releases of load as the tear wanders away from the interface and is guided back by the inspectors. To circumvent this problem, only that ADRIS output acquired during times of peel-strength testing when the tear ran along the rubber-to-metal bond(i.e., periods of no cutting) was used for correlations.

Listings of acquired data so selected are presented in the Addendum for the five sizes of roadwheel inspected. Due to this selection process, only about 22 percent of the acquired ADRIS output remained to be correlated. This data was subjected to three types of analysis. One type was a simple correlation of average peel-strength with average ADRIS output for each roadwheel size. Another type was correlation by least squares linear regression of peel-strength against ADRIS output. The third type was correlation of peel-strength failure with a specific pattern of ADRIS output amplitude and spatial extent.

5.2.1.1 Correlation of averages. For this type of correlation, the average measured peel-strength, average ADRIS estimated adhesion, and average ADRIS broadband reflection amplitude was computed for all the roadwheels of a given size for the sizes of 24 in by 2.12 in., 24 in. by 2-1/8 in., 24 in. by 3-3/4 in., 26 in. by 5-3/4 in., and 26 in. by 6 in.. Figure 5-2 shows the resulting trends. Included in Figure 5-2 are points representing adhesion acceptances and adhesion failures within the 24 in. by 2-1/8 in. roadwheel size group. The averages for the 24 in. by 2.12 in. and 24 in. by 2-1/8 in. roadwheels (including accept/reject subcategories) appear to lie along a common line expressed by the equation:

$$M = 0.514 * E + 20.6 \quad \text{Equation 5-1}$$

where      M is the measured peel-strength in lbs.  
              E is the ADRIS-estimated adhesion in lbs.

A surprising observation is that the 24 in. by 3-3/4 in. roadwheel averages appear to lie on this same line. Because the ADRIS monitors the roadwheels through a window of constant aperture, its report of bond strength is that of an adhesion for a given area, or an adhesion density. The peel test, on the other hand, records the roadwheel bond strength as integrated across the width of the wheel, or an absolute adhesion. To properly correlate estimated adhesion with measured adhesion, one must be normalized to the other by taking account of the relevant tread width. Since this is not done by the ADRIS, it would be expected that the 24 in by 3-3/4 in. roadwheel average measured adhesion would be 1.76 (= 3.75/2.125) times larger than given in Figure 5-2.

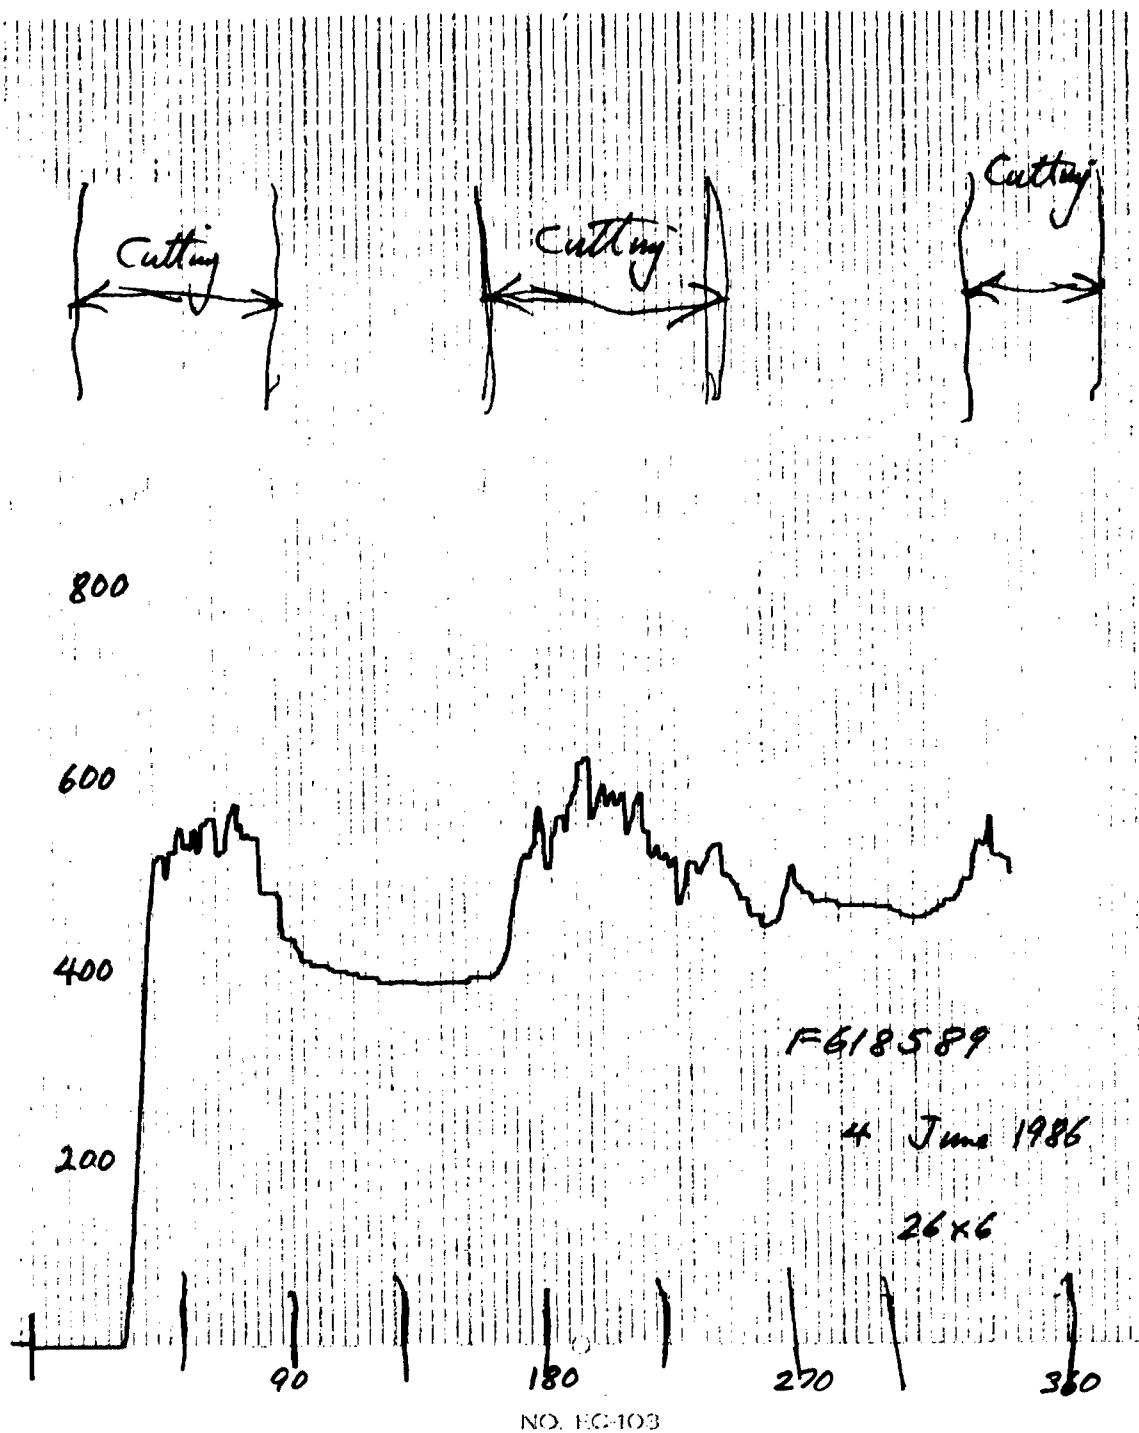

Figure 5-1 Typical Peel Record

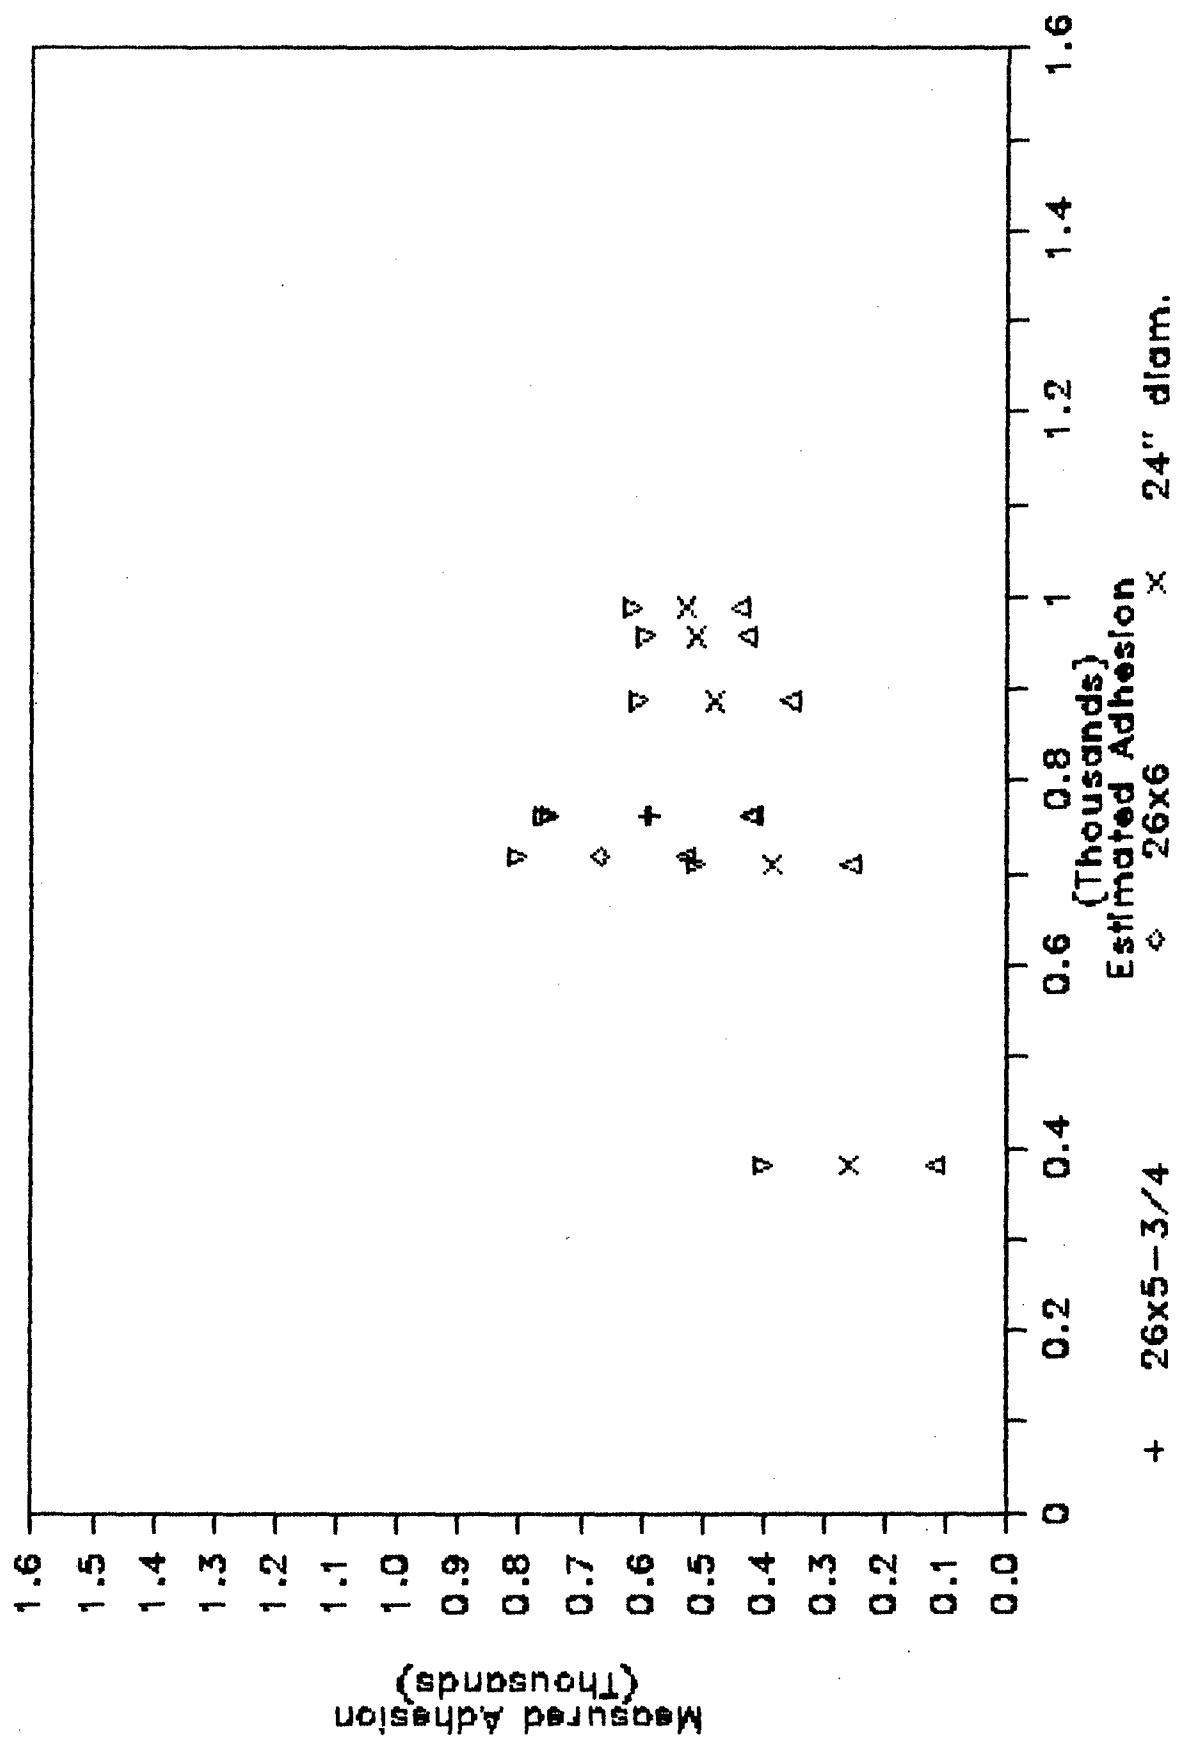

Figure 5-2 Measured Adhesion vs. ADRIS Estimate Averaged by Roadwheel Size

One possible explanation for the colinearity of 24 in by 3-3/4 in. roadwheel averages with other 24-inch-diameter roadwheel averages is that the 24 in. by 3-3/4 in. rubber-to-metal bonding is intrinsically weaker than that of the other 24-inch-diameter wheels. The greater tread width then brings the integrated adhesion up to that of the other size wheels. If this is the case, the average intrinsic bond would not be expected to vary without creating a severe disruption of production, and predictable correlation could be achieved by treating 24 in. by 3-3/4 in. estimates as if they were 24 in by 2.12 in. or 24 in. by 2-1/8 in. estimates and transforming each by Equation 5-1 to predict adhesion.

Another possible cause for colinearity of the 24-inch-diameter roadwheel averages would be that the adhesion estimation relations developed using 26 in. by 5-3/4 in. roadwheel data (presented in par. 5.1.1) are not valid for estimating 24 in. by 3-3/4 in. or other 24-inch-diameter roadwheel bond strength. In fact, they may be overestimating 24 in. by 3-3/4 in. bond strength or underestimating 24 in. by 2.12 in. and 24 in. by 2-1/8 in. bond strength. If this is the case, the relations must be modified. The simplest modification which would achieve the desired goal would be to transform each relation by using Equation 5-1 as was discussed above.

A third possible cause of the 24 in. by 3-3/4 in. roadwheel averages falling on a line common to other 24-inch-diameter roadwheel averages could be that the ADRIS is scanning through tread rubber of differing acoustic attenuation. This possibility was investigated using tread left over from peel tests and, although 24 in. by 3-3/4 in. tread rubber was found to be spectrally different from other 24-inch roadwheel tread rubber, no significant differences in attenuation were measured.

If the observation of colinearity among the 24-inch-diameter roadwheel averaged adhesions was a surprise, the appearance in Figure 5-2 of a distinct cluster of higher averaged adhesions for the 26-inch-diameter roadwheels was expected. It is presumed that the average measured and average estimated adhesions will, as was found for 24-inch-diameter roadwheel averages, correlate near the zero values. Consequently, the equations expressing these simple trends are approximately:

$$M = 0.776 * E \quad 26 \text{ in. by } 5\frac{3}{4} \text{ in.} \quad \text{Equation 5-2}$$

$$M = 0.928 * E \quad 26 \text{ in. by } 6 \text{ in.} \quad \text{Equation 5-3}$$

where      M is the measured peel-strength in lbs.  
              E is the ADRIS-estimated adhesion in lbs.

Note that the relation expressing 26 in. by 6 in. roadwheel averages (Equation 5-3) comes the closest to the estimation prediction ideal of a 1:1 ratio between estimated and measured adhesion averages. If this is used as a benchmark relation, then it should be expected that the slope of the 26 in. by 5-3/4 in. relation should be  $(5.75/6) * 0.928$  or 0.889 in value. This is quite different from the 0.776 implied by Figure 5-2. By similar calculations, it can be shown that the differences in the relations expressing 24 in. by 3-3/4 in. and 26 in. by 5-3/4 in. roadwheel averages

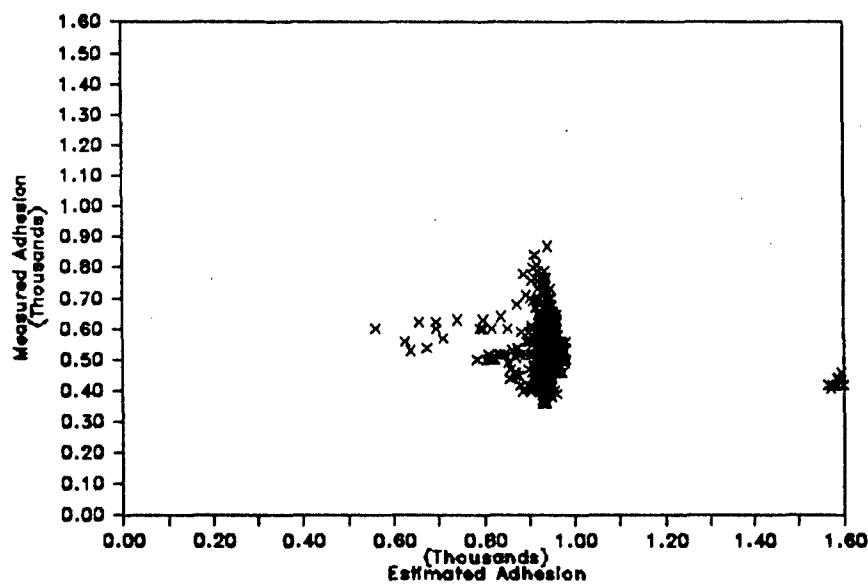

are accountable simply by the differences in their tread widths. This is not true for the 26 in. by 6 in. or for the 24 in. by 2-1/8 in. roadwheel averages. Their differences, with respect to the averages of other roadwheel sizes and with respect to each other, cannot be accounted for simply by their differences in tread width.

As discussed above, one explanation for the measured adhesion strength differences of roadwheels not being proportional to their tread width differences is that the intrinsic rubber-to-metal bonding is not identical. This hypothesis is not so attractive when considered for more than two groups of roadwheels. The fabrication processes used at RRAD are not that varied. It is known that two types of tread rubber are utilized -- type "B" for 24 in. by 2.12 in. and 24 in. by 2-1/8 in. and type "A" for all others. This can conveniently be invoked to explain the colinearity of the 24-inch-diameter roadwheel measured and estimated adhesion averages, but since the 26 in. by 6 in. and 24 in. by 3-3/4 in. roadwheels are built with a common tread rubber type, this cannot account for their observed differences.

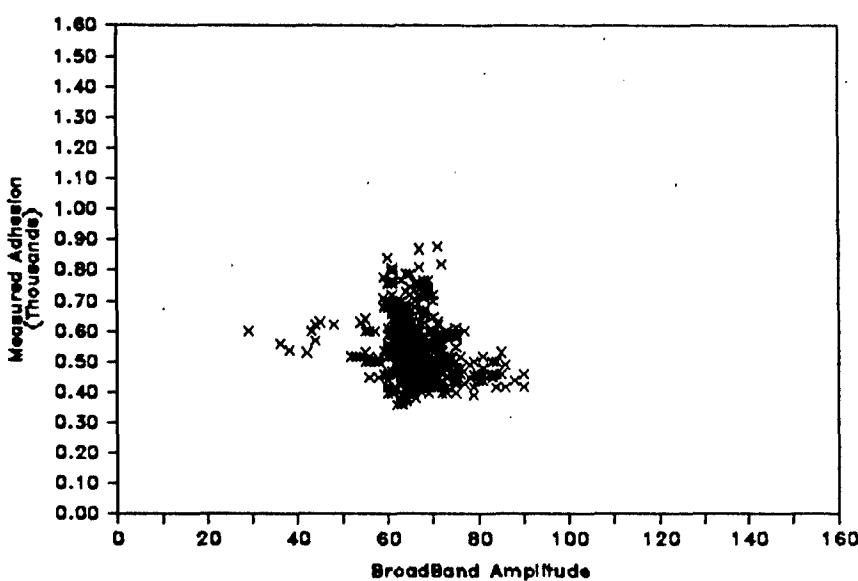

The other possible cause for the observed differences as discussed above is that the adhesion estimation relations developed using 26 in. by 5-3/4 in. roadwheel data (presented in par. 5.1.1) are not valid for estimating 26 in. by 6 in. roadwheel bond strength. If this is the case, the relations must be modified. The simplest modification which would achieve the desired goal would be to transform each relation by using Equation 5-1 as was discussed above. However, because the observed trends associated with the larger diameter roadwheels are not very securely established, and because there is such a large degree of variability of the averages, the question of to what the estimation relations should be transformed remains unanswered. A more precise type of correlation technique is attempted to establish this.

5.2.1.2 Correlation of least squares linear regression. For this type of correlation, the point-by-point measured peel-strength, ADRIS-estimated adhesion, and ADRIS broadband reflection amplitude and frequency ratios were computed for all the roadwheels of a given size for the sizes of 24 in. by 2.12 in., 24 in. by 2-1/8 in., 24 in. by 3-3/4 in., 26 in. by 5-3/4 in., and 26 in. by 6 in.. Figures 5-3 through 5-7 show the scatter plots of measured peel-strength against ADRIS-estimated adhesion for the five roadwheel sizes. On the basis of scatter plots, only the 24 in. by 2-1/8 in. roadwheels show any trend at all. This is because the three adhesion failures observed occurred in wheels of this size. The scatter among 24 in. by 2-1/8 in. roadwheel estimates does not appear to be any less than among other roadwheel sizes.

To quantify these results, least squares linear regression was applied to each size of roadwheel. The results are summarized in Table 5-2. It can be seen that trends do exist by which adhesion can be predicted by the ADRIS broadband and estimated adhesion outputs. The regressed linear relations bear no relation at all to the linear relations derived from the averages of measured and ADRIS-estimated adhesion described in par. 5.2.1.1. The

(b.) BroadBand

best coefficient of correlation is associated with the behavior of 26 in. by 5-3/4 in. roadwheels and it is a negative coefficient of unpromising low value. The regression line has a negative slope. This result is at such variance with expectations that the data was examined in more detail to discover the cause. Within each size category, roadwheels were further classified according to the slope of their relation between measured adhesion and an ADRIS output. As would be expected, this tended to reduce scatter and led to better correlations.

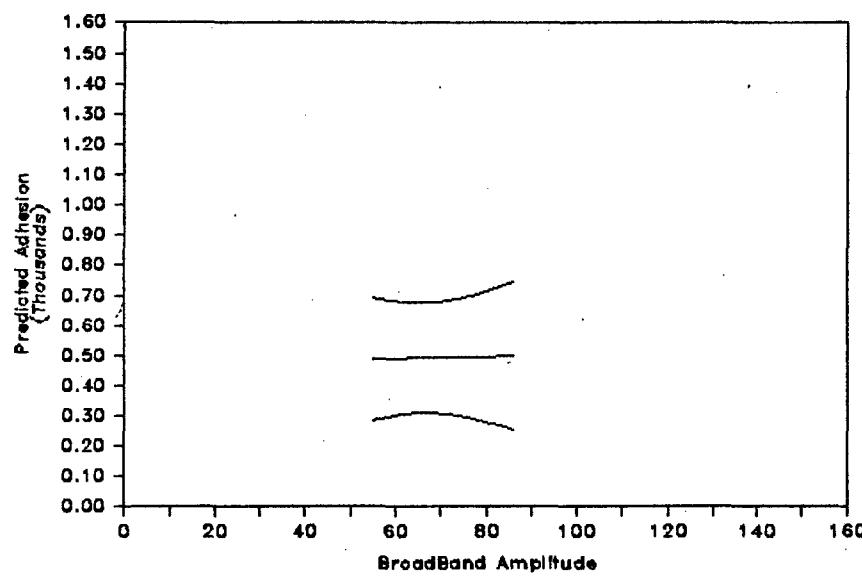

To further quantify these results, least squares linear regressions were applied to that class of each size of roadwheel that exhibited the least scatter in the adhesion vs. broadband amplitude relation (such relations typically had less scatter than the associated adhesion vs. estimate relations). These results are exhibited in Figures 5-8 through 5-12 and summarized in Table 5-3. Trends continue to exist by which adhesion can be predicted by one acquired and one derived ADRIS output. Except for 24 in. by 3-3/4 in. roadwheels, the regressed linear relations continue to bear no relation at all to the linear relations derived from the averages of measured and ADRIS-estimated adhesion described in par. 5.2.1.1. However, the best coefficient of correlation is associated with the behavior of 26 in. by 5-3/4 in. roadwheels and it is now a positive coefficient. No reason could be found why these subcategories existed. During the field test, parameters associated with Supply Quality Control (SQC) number, rubber quality, fabrication procedure, and even peel-test mechanics were identified and recorded. None could reliably be associated with the existence of distinct subclasses of ultrasonic adhesion behavior within roadwheel size groups. The best coefficient of correlation was found to be no larger than 0.80, signifying a low level of confidence in being able to use the regression line to predict adhesion on a wheel-by-wheel or point-by-point basis.

The fact that trends do exist relating ADRIS output to roadwheel adhesive strength implies, in spite of the poor degree of correlation, that there is an ultrasonic foundation upon which adhesion can be estimated. The selection mechanism for correlatable data described in the introduction of par. 5.2.1 has probably been insufficient to overcome the variability inherent in the mechanics of the destructive peel test. The measuring of adhesion as the entire width of the roadwheel tread is pulled away from the hub cannot easily be correlated with the intrinsically localized readings of the ADRIS. Also, until the independent variable of the peel test is linked directly to the circumferential motion of the roadwheel, instead of being inferred from the time base as it has been in this study, the correlation of ADRIS output with peel-strength can never be the best. In an attempt to bypass these limitations and to realize the goal of this project, a more detailed, less computerized type of correlation analysis was attempted.

5.2.1.3 Correlation of patterns. For this type of correlation, the measured peel-strength records and ADRIS printouts were manually examined for the existence of some unique pattern of broadband or frequency ratio behavior with respect to circumferential sampling which correlated reliably with the existence of peel-strength test rejection caused by failure of

(b.) BroadBand

adhesive strength. In the time period of this field test, only three roadwheels inspected by the ADRIS failed due to adhesion failure. Two of these wheels were deliberately made to possess low bond strength, but the third was a "natural" adhesion failure drawn from a production sample. A pattern of ultrasonic activity was found common to all these failures. This pattern was the presence of broadband amplitude less than a value of 40 for a contiguous circumferential extent equal to or greater than 7.5 inches (or  $36^\circ$  of arc). Figures 5-13, 5-14, and 5-15 show these patterns which predict adhesion failure. Implementing a filter for this pattern in the ADRIS will require programming a Test B analog for the broadband channel with support algorithms.

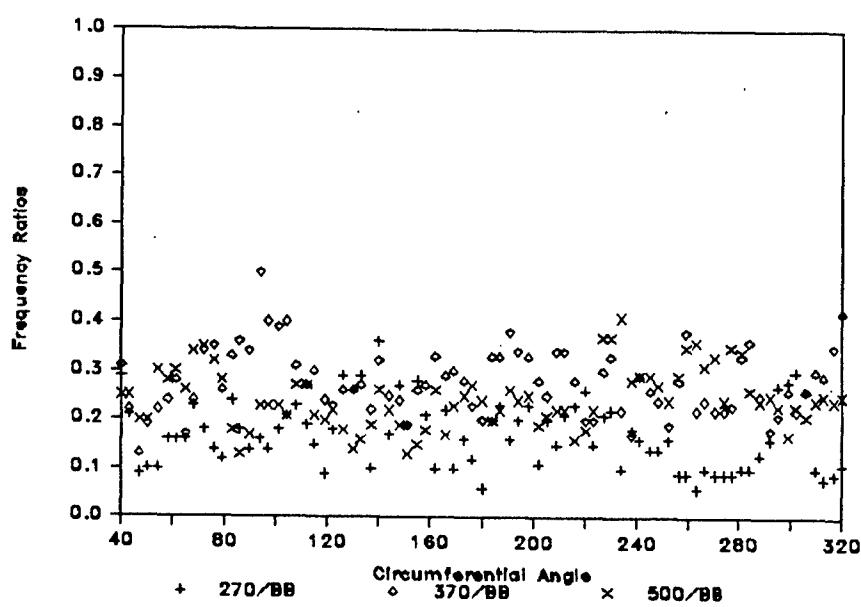

**5.2.2 Separation Detection.** If the ADRIS is to effectively replace the present peel-strength test, in addition to being able to predict the adhesive strength of the roadwheel rubber-to-metal bond as measured by the peel test, it must be able to detect the presence of rejectable separations in the rubber-to-metal interface as well as the quality assurance personnel do. Thus, the secondary task of the field test was to correlate the peel test separation discoveries with one or more of the ADRIS outputs to find which output yielded the best separation detection and to assess the reliability and accuracy of the detection.

As illustrated in Table 5-4, no ADRIS output provided a usable separation detection capability. The average percentage of separations detected was 40 percent with the larger diameter roadwheels having the larger percentage of detection. The circumstances under which separations were detected when they were detected reveals possible explanations for why the detection rate was so low and yields implications for ADRIS design to increase the detection rate. Figures 5-16 and 5-17 show the ADRIS broadband indication for the most unambiguous detections of separations. The RRAD quality assurance personnel referred to these as "trapped air" pockets. Each was a large diameter separation (0.75 inches or larger) and each was positioned such that it passed under the beam of the ultrasonic transducer during inspection. Invariably, ultrasonically undetected separations were smaller in diameter than 0.75 inches or did not pass under the transducer or both. Figure 5-18 illustrates the interesting case of a 1-inch-diameter separation located at  $210^\circ$  on the circumference which, being on the midline, passed between the beams of a twin transducer configuration. Nevertheless, its diameter was sufficient enough to cause it to register in one or both transducers and thus be detected.

These results imply that the rate of ADRIS-detected separations can be increased by the appropriate modification of ADRIS configuration and firmware. The first modification necessary is one that allows ultrasonic scanning of the entire roadwheel tread. The present ADRIS configuration limits scanning to one or two parallel bands each of 1-inch width around the roadwheel circumference. Incorporation of a linear array of transducers will permit complete coverage of the roadwheel with the guarantee that any separations will fall within an ultrasonic beam sometime during the inspection. Such a modification will require reprogramming of the present system to treat each transducer as an independent channel of input.

As discussed in par. 5.2.1, averaging of data among the transducers does not affect the ability of the ADRIS to predict rejectable adhesion, but it may affect the detection of separations, especially if more than two transducers are used. Therefore, the controlling microcomputer must process acquisitions for separation detection as independent channels. This will place such an extra computational load on the present microprocessor hardware that the required inspection time may have to be increased almost proportionally, or a faster microprocessor family will have to be installed.

In addition to implementing a linear transducer array for separation detection, the diameter of each transducer beam will have to be made smaller to increase the resolution of the inspection. RRAD peel test requirements presently reject roadwheel lots on the detection of separation(s) of an apparent diameter of 0.125 inch or larger. Thus, the ADRIS must be able to resolve to this size. As presently configured, the ADRIS acquires ultrasonic reflection data from an area approximately the diameter of 1 inch for each pulse. As a consequence, any separation of 0.125 inch diameter reflecting a fraction  $s$  of well-bonded ultrasonic energy  $N$  will cause the acquired signal to be reduced by a factor:

$$\frac{63}{64} * N + \frac{s}{64} * N$$

Thus, if the separation is reflecting a fraction very nearly zero, the resulting amplitude of the entire acquired signal would only be 0.984, an insignificant reduction. Such a separation would almost certainly go undetected. However, as the effective transducer beam width approaches the width of the minimum rejectable separation, a greater fraction of the separation's signature weights the acquisition aperture and the net signature increases in significance, increasing detection probability.

Another firmware modification required will be that supporting a higher resolution in the averaging of acquired input to produce sampled values. The present computation of samples yields a maximum resolution of 0.754 inch to 0.817 inch around the circumference for 24 and 26-inch-diameter diameter roadwheels respectively. If it is desired to detect separations of diameter as small as 0.125 inch, the computation of averages must not extend beyond this limit. This sixfold increase in samples will place even heavier loads on the microcomputer's computational and memory resources. It is estimated that present address availability is insufficient for such expansion and that a more powerful microprocessor family will have to be incorporated.

**5.2.3 Cosmetic Fault Detection.** If the ADRIS is required to replace the present peel-strength test, in addition to being able to predict the adhesive strength of the roadwheel rubber-to-metal bond as measured by the peel test and to detect the presence of rejectable separations in the rubber-to-metal interface as well as the quality assurance personnel do, it

may also be required to detect the so-called "cosmetic faults." These are typically contamination of the bond interface by foreign material, poor joining of the rubber tread splice, and other instances of poor fitting or workmanship revealable only upon destructive testing of the roadwheel. During this field test, no evidence was found to suggest that the ADRIS could detect any of these conditions. However, it is possible that performance in this area could be improved by incorporation of the modifications discussed in par. 5.2.2 to increase the resolution of the ADRIS to detect the presence of separations.
